ISSUED BY	AutoOffice Sp. z o.o., Opole, Poland
CLASSIFICATION	Confidential

AutoOffice at a glance

AutoOffice Sp. z o.o. is a Polish software company based in Opole. It writes and operates its own software, and it builds software that connects other companies' systems to the AI assistants their people already use.

Two lines of business

iKrystyna — our own software-as-a-service

iKrystyna is AutoOffice's own product for automated accounting and the company's core business. It is a service that companies subscribe to, not a project delivered once: AutoOffice writes it, hosts it, operates it and answers for it. Over twenty small and mid-size companies are registered on it. The connector platform described in this dossier is the same one that serves it.

Bespoke AI integration

Alongside the product, AutoOffice carries out bespoke AI integration work for a small number of established mid-size companies. That work is done under non-disclosure, which is why the clients are not named here.

What we specialise in

Our speciality is **connectors**: software that lets a company's own AI assistant — Claude, ChatGPT or Microsoft Copilot — work safely with that company's business systems. They are built on the **Model Context Protocol** (MCP), an open, published standard for connecting AI assistants to external systems and data. Because the protocol is open and not owned by AutoOffice, a connector is not tied to one assistant, one vendor or one supplier.

SPECIALITY

Connectors on the open Model Context Protocol

What we build — one platform, several connectors

A connector sits between the assistant a company already pays for and the system where its work actually lives. It is the place where sign-in, permissions and the audit trail are enforced.

FIGURE 1 Only the middle block is ours; the assistant and the system of record stay with the customer.

Three instances of the same platform

All three run the same server framework on the Model Context Protocol, the same sign-in and role model, and AutoOffice’s shared result-card library.

CONNECTOR	DOMAIN	BUILT FOR
iKrystyna Connect	Accounting	AutoOffice’s own accounting service — the owner of a company asks about their own books and gets figures from the live ledger.
Vendo Connect	ERP	CFI, the maker of the Vendo ERP system — users of Vendo work with ERP data through an AI assistant.
LC Connect	Lead intelligence	Laser Components — finding, enriching and organising leads.

What sits inside the middle block

- **Sign-in.** People sign in through the identity provider the company already uses.
- **Roles and permissions.** What the assistant may see and do follows the role of the person asking, not the wording of the question.
- **Audit trail.** Every change is recorded, including attempts that were refused.
- **Interactive result cards.** Answers come back as tables and figures rendered inside the conversation and built from the system of record, not from the model’s general knowledge. Figures 3 and 4 in this dossier are two such cards.

Bring your own intelligence

The customer keeps its own AI subscription and its own choice of assistant. AutoOffice charges no per-user fees and resells no AI capacity. The connector’s source code lives in a repository the customer controls, and the data stays in the customer’s system of record.

iKrystyna

Our software-as-a-service for automated accounting — and our core business

iKrystyna is AutoOffice's own software product and its core business: statutory accounting for Polish limited liability companies (sp. z o.o.), run on software AutoOffice built itself. Documents go to one e-mail address in any format; back comes a single message: what is missing, what it blocks, by when. Books, VAT, payroll, declarations and deadlines are kept by the system; an accountant reviews what the law or judgement requires. More than twenty companies are registered.

The automated accounting engine

Documents arrive from KSeF (Poland's national e-invoicing system), from e-mail and scans, and from banks. Each is stamped into a processing registry before it is touched; extraction reads type, header and lines, then tax-ID, VAT-rate and duplicate checks run. Posting into the double-entry ledger is deterministic: a rule set and account dictionary, not a model guess. Payroll covers all Polish contract types and computes ZUS (state social insurance) contributions; bank statements are matched against invoices.

Month-end is gated: the bank account must reconcile to the statement to the cent, and ledger, VAT records and KSeF must agree. Only then are the JPK_V7M file (the monthly VAT ledger and return), KSeF submissions and ZUS and income-tax declarations generated. Anything ambiguous goes to a person, every outgoing message is human-approved, and a person signs and files the declarations.

FIGURE 2 The iKrystyna pipeline, from source document to filed declaration, with the accountant in the loop.

iKrystyna Connect

Connect is an MCP server that lets the owner query their own books from Claude or ChatGPT in plain language: what is due this month, what sits in the KSeF inbox, last month’s profit and loss, overdue receivables, the state of the close, whether a counterparty is on the Ministry’s VAT white list. Answers are figures and interactive widgets built from the live ledger, not the model’s general knowledge. Forty-five tools are registered, read-only by design; issuing a sales invoice is the one exception, a prepare → confirm → issue sequence. Every other change is an audited request to the office.

Connect is built on the same platform as Vendo Connect and LC Connect — the same server framework on the Model Context Protocol, the same OAuth sign-in and role model, an audit trail in each, and AutoOffice’s shared result-card library for everything the assistant displays. It differs only where the business does: which system it reads and which questions it answers.

The two figures below are answers returned by iKrystyna Connect inside an AI assistant. They are result cards built from the ledger: the assistant does not compute or estimate the numbers, it asks the connector for them and renders what comes back. The interface is shown in Polish, as deployed.

Engineering facts

Isolation in the database, not in application code

PostgreSQL row-level security covers the company-scoped tables; Connect takes the tenant from the JWT, never from a tool argument.

Tamper-evident audit trail

An immutable log with a SHA-256 hash chain records financial actions; middleware logs every tool call with user, company and arguments.

Tested on CI

238 pytest files under tests/, including a tenant-isolation suite, behind 12 GitHub Actions workflows.

Operated as a supervised service

Hosted in the EU (Warsaw). Every component runs as a supervised service that restarts on failure; all traffic is encrypted with automatically renewed certificates.

Monitored and backed up

Prometheus, Grafana and Loki scrape the API, MCP server and PostgreSQL; timers watch filing deadlines and anchors; data is held in the EU, with nightly off-site backups and GDPR purges.

SECTION 4

Bespoke solutions

Beside its own product, AutoOffice carries out bespoke AI integration work for a small number of established mid-size companies. That work is done under non-disclosure.

Typical scope of an engagement

- A connector to an existing system.
- Identity integration — people sign in with the accounts they already have.
- A role model, so that what an assistant may see and do follows the role of the person asking.
- An audit trail.
- Operation and support of the running service.

Reference client

CFI is AutoOffice's principal client and the maker of the Vendo ERP system.

For CFI, AutoOffice develops applied-AI solutions around the ERP. Among them is **Vendo Connect**, the connector that lets users of Vendo ERP work with their data through an AI assistant. The worked example below comes from that connector.

CLIENT CFI WEB www.cfi.pl PRODUCT Vendo ERP

SECTION 6 · ADVANCED EXAMPLE, FROM VENDO CONNECT

From a CAD file to a production routing, in one step

An engineer drops a STEP file into the chat. The connector stores it per customer and immediately starts a background worker: the solid model is converted to a web-viewable 3D mesh, and every part in it is rendered as a dimensioned 2D drawing — front, top and side, with overall dimensions in millimetres and a sheet-thickness callout for flat parts. For this rotor assembly the conversion takes well under a minute.

The connector then reads the assembly tree straight out of the STEP: 46 bill-of-material positions, 12 sub-assemblies, hierarchical item numbers (1 / 1.1 / 1.1.1), a quantity on every line (edge multiplicity × parent quantity), and a bounding box measured from each part's geometry. Every leaf is classified as made in-house or bought in, and gets a suggested operation list.

Finally the routing: operations in sequence, candidate workstations from the plant's machine list, and setup/unit times — presented as a proposal. Nothing is written into the ERP until a person confirms it.

Interface shown in Polish, as deployed.

FIGURE 5 The rotor assembly as the connector's 3D viewer shows it in the chat, converted automatically from the uploaded STEP file. Rotate, zoom, no CAD licence and no plug-in required.

How we work

Sign-in	Through the customer's own identity provider. No separate password estate.
Permissions	Role-based. What the assistant may see and do follows the role of the person asking.
Audit trail	Every change is recorded, including attempts that were refused.
Backups	Nightly.
Monitoring	Automated: every five minutes a monitor signs in and runs a query, so a failure is found by us before it is reported by a user.
Source code	Held in the customer's own repository.
Commercial terms	A flat monthly service fee with included development hours. No per-user fees.
Exit	Without lock-in.

The detailed service terms — scope, service levels, response times and the commercial schedule — are carried by a separate document, the **LC Connect Service Package**.
